

1. How do the concepts/aspects/components from this particular topic improve upon a management information system?

-Based on the video, MIS improves because it doesn't just store data, it helps managers make decisions using reports like summary and exception reports. For example, instead of checking all sales data manually, managers can look at summarized reports to quickly understand performance. If there's a problem, like low sales, exception reports highlight it immediately. Because of this, decisions become faster and more accurate.

2. Can the discussed concepts/aspects/components be implemented across all possible businesses and/or organizations? How?

-Yes, but it depends on the size of the business. Small businesses can use simple systems like basic sales and financial tracking, while larger companies use more advanced MIS that connects different departments. The important idea is that all businesses can use MIS to support decision-making, just in different levels of complexity.

3. Can these concepts/aspects/components be combined with other types of management information systems previously discussed? How?

-Yes. MIS works together with other systems. Operational systems collect daily data, like sales or inventory. Then MIS processes that data into useful reports. After that, top management can use those reports for long-term planning.

4. Are there possible risks and/or limitations to consider before implementing these concepts/aspects/components? What are they?

-Yes, there are some limitations. First, if the data entered is wrong, the results will also be wrong. Second, MIS can be expensive and hard to maintain. Third, there are security risks since business data is sensitive. Also, the system cannot decide on its own, it only helps managers. The final decision still depends on the person using it.
